AiXplore App Logic

Oct 18, 2026 · @Rita

AiXplore runs one loop: it learns about the senior, suggests a few activities, helps her get there, checks how it went, and uses the answer to make a better suggestion next time. The prototype is set in North York, in English, Mandarin and Tagalog.

Who uses it

The senior is the main user; the adult child sets her up once and steps back.

User	What they do	How often
Senior (Mei)	Gets suggestions, asks questions, RSVPs, gives feedback	Weekly
Adult child	Sets up her profile and language, then steps back	Once
Our team (later, partners)	Adds and verifies activities in the feed	Ongoing, behind the scenes

The three pieces of data

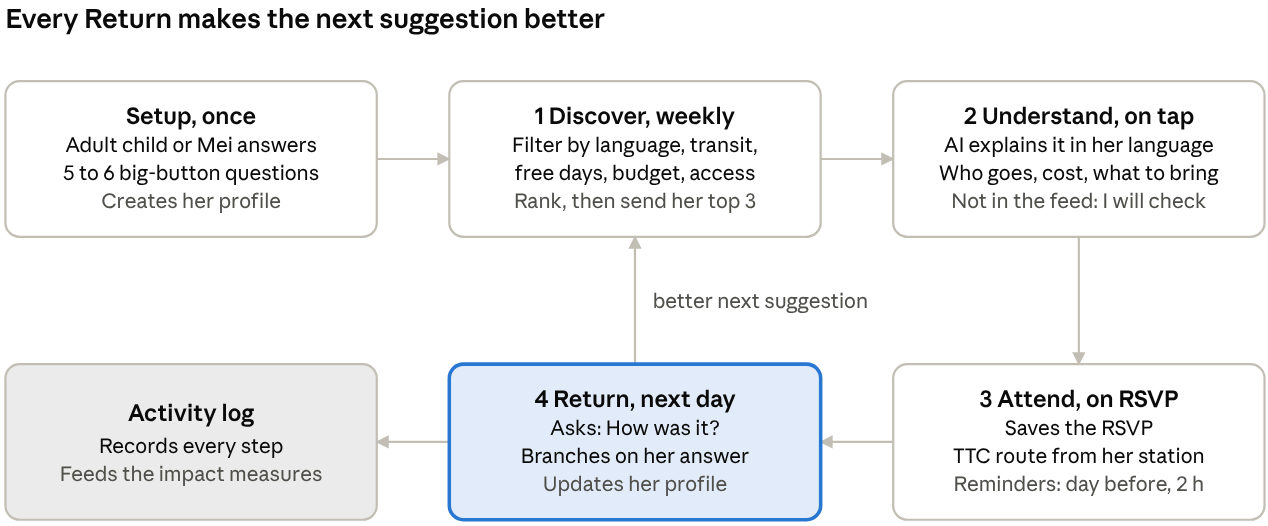

Everything the app does reads from or writes to one of these three.

Data	What it holds
Senior profile	Language, neighbourhood or nearest TTC station, interests, available days, budget, mobility needs, comfortable going alone
Activity feed	Our verified spreadsheet: name, organizer, address, day and time, cost, language spoken, age mix, people come alone, what to bring, TTC route, accessibility, date last verified

Data	What it holds
Activity log	What was suggested, opened and RSVP'd to, whether she went, her feedback, how many times she has returned

The flow, step by step

Setup happens once; Discover, Understand, Attend and Return then repeat every week, and every step is written to the activity log.

AiXplore loop · setup once, then 4 steps that repeat

How Discover ranks. After filtering out what doesn't fit, it ranks what's left by:

- match with her interests
- "people come alone: yes," weighted higher for new users
- her past feedback (more like what she liked, less like what she didn't)
- a bit of novelty, so it isn't always the same type

Attend can also show "2 others from AiXplore are going," only for people who opted in.

How Return branches:

Her answer	What the app does
Liked it	Suggests the next session and offers a standing reminder
It was OK	Suggests something similar but different
Didn't like it	Asks why with simple buttons (too far, language, felt alone, not interesting), updates her profile, tries a different type
Didn't go	Asks what got in the way and fixes it next time (closer location, a buddy, an earlier reminder)
No reply	One gentle nudge two days later, then waits for next week's suggestions

What the AI does, and what simple rules do

Rules pick the activities; the AI explains and listens. Facts come only from the verified feed, which is our answer to "why not ChatGPT?"

Job	Handled by	Why
Filtering and ranking activities	Simple rules	Predictable, explainable, can't invent events
Translation and "what to expect" explanations	AI	Natural language in her language
Understanding free-text requests ("something with music near Finch")	AI	Turns her words into filters
Reading her feedback ("the people were nice but it was far")	AI	Picks out what to update in her profile
Facts (times, places, cost)	Feed only	The AI may only use verified data; if the feed doesn't cover a question, it says "I'll check with the organizer"

How it connects to our impact measures

The activity log produces every impact measure automatically.

Measure	Read from the log as	SDG
% trying a new community activity within 30 days	First RSVP plus confirmed attendance	10.2 Reduced Inequalities
% attending without family help	RSVP and attendance with no adult-child involvement	10.2 Reduced Inequalities
% returning to the same activity 3+ times	Return count per activity	10.2 Reduced Inequalities; 3.4 Good Health and Well-being
North star: meaningful participations per active user per month	Attended plus a completed Return step	—

What to simplify in the prototype

The demo needs only the loop working end to end on real North York data; everything else is a next step we explain.

Build:

- A pre-filled profile for Mei
- 15–25 real North York activities in the feed
- Simple filtering and ranking
- AI explanations in Mandarin and Tagalog
- Simulated reminders (a "show tomorrow's reminder" button)
- The Return branching
